Scapholunate advanced collapse (SLAC) is the most common form, followed by scaphoid non-union advanced collapse (SNAC). Other post-traumatic causes such as intra-articular fractures of the distal radius or ulna can also lead to wrist osteoarthritis, but are less common.

It is most commonly due to ligamentous injury of the scapholunate interosseous ligament or to scaphoid non-union advanced collapse. In DISI there is dorsal angulation of the lunate as it rotates about its articulation with the radius.

Post-traumatic Scapholunate Advanced Collapse of the Wrist ...

Scapholunate Advanced Collapse (SLAC wrist) is due to advanced injury of the scapholunate and volar radioscapholunate ligaments which may lead to rotatory subluxation of the scaphoid and scapholunate dissociation. As in this severe case, the capitate may migrate proximally into the widened scapholunate space and articulate with the distal radius.

SNAC (Scaphoid Nonunion Advanced Collapse) - Hand ...

Scapholunate advanced collapse (SLAC) describes a characteristic degenerative clinical wrist condition of progressive instability, deformity, and arthritis affecting the radiocarpal and midcarpal joints of the wrist.

Introduction: A condition of progressive instability causing advanced arthritis of radiocarpal and midcarpal joints. describes the specific pattern of degenerative arthritis seen in chronic dissociation between the scaphoid and lunate; Pathoanatomy chronic SL ligament injury creates a DISI deformity. scaphoid is flexed and lunate is extended as scapholunate ligament no longer restrains this ...

Scapholunate advanced collapse | Radiology Reference ...

Scapholunate advanced collapse (SLAC) pattern of wrist arthritis was described in 1984, when Watson and Ballet reviewed 4,000 wrist radiographs and found degenerative arthritis in 210 cases and, of these, 57% were arthritis between the scaphoid, lunate, and radius. 1, 4 Scapholunate ligament (SL) tears are the most common wrist ligament injury caused by rupture of the intrinsic ligament connecting the scaphoid to the lunate. 5, 6 Therefore, attenuation of the SL, whether traumatic or ...

Nearly 90% of the degenerative changes observed in patients with osteoarthritis of the wrist follow three predictable patterns, the most common of which is “scapholunate advanced collapse (SLAC)” wrist, coined by Watson and Ballet in 1984. 1 Arthritic changes initially involve the radioscaphoid joint, and as cartilage disappears, the radial side of the wrist loses support. The capitate slides away from the radial side of the lunate, which in turn, leads to degeneration of the ...

Scapholunate Advanced Collapse Pattern of Osteoarthritis
Chronic scapholunate dissociation leads to a predictable pattern of degenerative changes in the radiocarpal and midcarpal joints. The incongruent joint surfaces between the radius and malrotated scaphoid, as well as those between the head of the capitate and dorsiflexed lunate, lead to osteoarthritis.

Scaphoid non-union advanced collapse (SNAC) is a complication that can occur with scaphoid fractures, specifically non-union of scaphoid fractures. It is essentially the same sequela of wrist injury causing scapholunate dissociation as seen in scapholunate advanced collapse (SLAC).

Scapholunate advanced collapse: a pictorial review
Scapho-lunate advanced collapse arthritis or SLAC occurs as the result of unrecognised injury to the ligament between the scaphoid and the lunate. This ligament is a very important one in the wrist and is the most frequently injured in falls onto the outstretched hand.
