There are four different quantum numbers needed to specify the state of an electron in an atom. 1. The principal quantum number n gives the total energy. 2. The orbital quantum number gives the angular momentum; can take on integer values from 0 to $n-1$. Hydrogen Atom: Schrödinger Equation and Quantum Numbers | 13.

The Schrödinger approach to Quantum Mechanics is known as wave mechanics. The Schrödinger formulation is in terms of states of a system which are represented by complex functions defined in Euclidean space, $\psi(r)$ known as wave functions and measurements are represented by linear differential operators.

Quantum mechanics gradually arose from theories to explain observations which could not be reconciled with classical physics, such as Max Planck's solution in 1900 to the black-body radiation problem, and from the correspondence between energy and frequency in Albert Einstein's 1905 paper which explained the photoelectric effect.

Here are my solutions to various problems in David J. Griffiths's excellent textbook Introduction to Quantum Mechanics, Second Edition. Obviously I can't offer any guarantee that all the solutions are actually correct, but I've given them my best shot. After some consideration, I've decided to repost this index to the solutions.

Griffiths: Introduction to Quantum Mechanics

Much insight in quantum mechanics can be gained from understanding the closed-form solutions to the time-dependent non-relativistic Schrödinger equation. It takes the form where ψ is the wave function of the system, H is the Hamiltonian operator, and t is time.
